
CS131: Programming Languages

— Fall 2015
— Week #7

Today

- HW 5 Roundup
- Python & Project Intro
- Midterm

HW 5 Finer Details

- Commutativity of lambda args & let bindings

```
(lambda (x y) (+ x y)) ; (lambda (y x) (+ y x))
```

```
(let ((a 1) (b 2)) (+ a b)) ;
```

```
(let ((b 2) (a 1)) (+ a b))
```

- Do we say they're the same and compare bodies? Or different?
 - A: Different

```
(if TCP (let ((a 1) (b 2)) (+ a b))
```

```
(let ((b 2) (a 1)) (+ a b)))
```

HW 5 Finer Details

- If every element of the list is different, do we do comparison element-wise or on the whole list?

`(compare-expr '(cons 1 2) '(+ 3 4))`

- A: Don't need to be smart here:

`((if TCP cons +) (if TCP 1 3) (if TCP 2 4))`

HW 5 Finer Details

- `#!r6rs` stuff
- Implement one-armed if (and we might test it)
 - But! the test cases you submit don't have to demonstrate that it works.
- You can test your file and submit without all the `#!r6rs` stuff

CS 131 Discussion 8

Winter 2015

Announcements

- **Project**
 - Thursday, March 05, 23:55

Midterm

- Please see CCLE announcement for details
- I graded: questions 1, 3, 4
- Prof. Eggert graded: questions 2, 5

Python

Variables & Printing

Variables do not have to be declared before assignment, and can be rebound

```
>>> x = 1 + 2
>>> x
3
>>> x = "foo"
>>> x
'foo'
```

Strings can be enclosed in single, double, or triple (""") quotes (which can span across multiple lines)

```
>>> print "Mary's car"
Mary's car
```

```
>>> print("""Mary's "beautiful" car
was worth %s dollars""" % (x))
Mary's "beautiful" car
was worth 3 dollars
```

Dictionaries, List, Tuple

Dictionary elements can be added easily

```
>>> w = {"Mary" : 1, "George" : 2,  
"Martin" : 3}
```

```
>>> w  
{'Martin': 3, 'Mary': 1, 'George': 2}
```

```
>>> w.get("Martin")  
3
```

```
>>> w["Betty"] = 4  
>>> w.get("Betty")  
4
```

You can use anything as key/value, as long as the key is hashable (eg. a list is not)

```
>>> y = {x : 1, "bar" : [1, 2, "baz"], 42 : (1,1)}  
>>> y  
{42: (1, 1), 3: 1, 'bar': [1, 2, 'baz']}
```

```
>>> z = y.get(42)  
>>> z.count(1)  
2
```

Both list and tuple can have any elements inside

```
>>> y.get("bar")[1:3]  
[2, 'baz']
```

```
>>> y.get("bar")[2]  
'baz'
```

Control Flow Statements

Empty lists & tuples, or null objects are false

```
>>> if ([] or () or None):  
    print "() or [] or None is true"  
else:  
    print "() and [] and None are false"
```

() and [] and None are false

```
>>> if 3 != 4:  
    x = "foo"  
else:  
    x = "bar"
```

```
>>> x  
'foo'
```

```
>>> z = [1,2,3]  
>>> for i in z:  
    print i
```

```
1  
2  
3  
>>> i  
3
```

```
>>> for j in y.iteritems():  
    print j
```

```
(42, (1, 1))  
( 'foo', 1)  
( 'bar', [1, 2, 'baz'])
```

Note: Indenting is crucial! **All** statements in the same level **must** have the same indentation

Functions

You can return different values, or no value

```
>>> def inverse(x):  
    if x == 0:  
        print "Oops!"  
        return  
    if x == 1:  
        return "It's the same!"  
    print "the answer is:"  
    return 1./x
```

```
>>> inverse(0)  
Oops!  
>>> inverse(1)  
"It's the same!"  
>>> inverse(2)  
the answer is:  
0.5
```

Nameless functions are also possible, if the function body is to return a single expression

```
>>> (lambda x:x*x)(3)  
9
```

```
>>> def applyTwice(f, x):  
    return f(f(x))
```

```
>>> applyTwice((lambda x: x*x), 2)  
16
```

```
>>> f = lambda x:x*x
```

```
>>> applyTwice(f, 2)  
16
```

Classes

```
>>> class BaseClass(object):  
    def __init__(self, argx):  
        self.x = argx
```

```
>>> foo = BaseClass(3)  
>>> foo.x  
3
```

Class members are always accessible

```
>>> foo.x = 5
```

You can also add members to an instance

```
>>> foo.y = 6  
>>> bar = BaseClass(8)  
>>> bar.y #This results in a error!
```

```
>>> class ChildClass(BaseClass):  
    def __init__(self, argx, argy):  
        super(ChildClass,self).__init__(argx)  
        self.y = argy  
    def getX(self):  
        return self.x  
    def getY(self):  
        return self.y
```

```
>>> baz = ChildClass(1,2)  
>>> baz.__dict__  
{ 'y': 2, 'x': 1}  
>>> baz.getX()  
1
```

Twisted

Event-Driven Architecture

- Events can enter the event queue
- The event in the front of the queue is pass to a protocol, which processes the event

Reactor, Protocol, Factory, Transport

Reactor event loop

- Waits on and dispatches events to event handlers

Protocol

- Must handle these events:
makeConnection, connectionMade, dataReceived, connectionLost

Protocol Factory

- Builds new instances of protocols (for each new connection)
- Saves persistent information

Transport

- Represents the connection between two endpoints
- Has following methods, which can be called by a protocol:
write, writeSequence, loseConnection, getPeer, getHost

Example: chatserver.py

```
from twisted.internet.protocol import Factory
from twisted.protocols.basic import LineReceiver
from twisted.internet import reactor

class ChatProtocol(LineReceiver):
    def __init__(self, factory):
        self.factory = factory
        self.name = None
        self.state = "REGISTER"

    def connectionMade(self):
        self.sendLine("What's your name?")

    def connectionLost(self, reason):
        if self.name in self.factory.users:
            del self.factory.users[self.name]
            self.broadcastMessage("%s has left the channel." % (self.name,))

    def lineReceived(self, line):
        if self.state == "REGISTER":
            self.handle_REGISTER(line)
        else:
            self.handle_CHAT(line)

    def handle_REGISTER(self, name):
        if name in self.factory.users:
            self.sendLine("Name taken, please choose another.")
            return
        self.sendLine("Welcome, %s!" % (name,))
        self.broadcastMessage("%s has joined the channel." % (name,))
        self.name = name
        self.factory.users[name] = self
        self.state = "CHAT"
```

```
    def handle_CHAT(self, message):
        message = "<%s> %s" % (self.name, message)
        self.broadcastMessage(message)

    def broadcastMessage(self, message):
        for name, protocol in self.factory.users.iteritems():
            if protocol != self:
                protocol.sendLine(message)

class ChatFactory(Factory):
    def __init__(self):
        self.users = {}

    def buildProtocol(self, addr):
        return ChatProtocol(self)

reactor.listenTCP(8000, ChatFactory())
reactor.run()
```

port #

Project

Your task

- Investigate Twisted
- Build prototype of an event-driven application with an “application server herd” architecture. Five servers and non-predetermined number of clients
- Make comment on Twisted’s usefulness and compare to Node.js (Javascript, also event-driven)

Application Server Herd

Example with 3 servers and 3 clients:

Your Prototype

- 5 servers: 'Alford', 'Bolden', 'Hamilton', 'Parker', 'Powell'
 - Alford talks with Parker and Powell
 - Bolden talks with Parker and Powell
 - Hamilton talks with Parker
- Each server should accept TCP connections from clients (eg. via telnet)

Client

- A client can send its location to the server:

```
IAMAT kiwi.cs.ucla.edu +34.068930-118.445127 1400794645.392014450
```

- Or it can query for places near a client's location:

```
WHATSAT kiwi.cs.ucla.edu 10 5
```

Server

- Upon receiving an IAMAT from client C, the server sends C, and the server's neighbours:

AT Alford +0.563873386 kiwi.cs.ucla.edu +34.068930-118.445127 1400794699.108893381

- Upon receiving an WHATSAT from client C, the server queries Google Places and returns the location of the queried client (via AT), followed by the JSON returned by Google Places
- Upon receiving an AT from another server S, this server must check the timestamp of the AT, before storing the new location information and relaying the message to its neighbours

Painfully-Detailed Step by Step Tutorial to Run the Example in the Spec
